# 1 Introduction

Observation of Photometric Standard Stars is necessary if absolute photometry is required from imaging observations. These Standard Stars are typically taken from published catalogues such as the widely used one by Landolt [1]. Since the position and brightness of these stars are catalogued, it makes sense to have pre-prepared Observation Blocks (OBs) to save observers having to make the same ones for each run.

## 1.1 Purpose and Scope

This document describes a set of OBs has been produced to be used for the observation of fields containing photometric standard stars using EFOSC2 on the NTT. It is based on a previous version covering the fields for EMMI and SuSI2 at the NTT, and EFOSC2 on the 3.6m, but for the completely updated OBs for the new field of view of EFOSC2 at the NTT. The accompanying reference material gives details on how these OBs are made, and provides individual information (finding charts and tabulated photometry) for each standard field. This information is intended to be of help to those involved in the acquisition, analysis, and quality control of photometric observations obtained with these instruments.

## 1.2 Applicable Documents

LSO-LIS-ESO-40500-0001

## 2 Selection of Fields

The selected standard fields have been taken from Landolt's 1992 catalogue [1], and contain stars mostly in the range  $11.5 < V < 16.0$ . With the exception of T Phe, all the fields are located near the celestial equator. The fields here are based on those given for EMMI/SuSI2/EFOSC2 in LSO-LIS-ESO-40500-0001, but with updated field centres for EFOSC2 at the NTT. The centres of the fields have been chosen so that at least 3 standard stars listed in Landolt's paper are contained within a single frame of EFOSC2. Whenever possible, these stars cover a fairly large range in colors, although this is obviously limited by the small number of stars usually fitting within the field of view. Given its sensitivity, the brightest standard stars in Landolt's list are inappropriate to be used with EFOSC2. For this reason, standard stars brighter than  $V \simeq 11$  have been generally left out of the selected fields. The list of the field centres for EFOSC2 is given in Table 1. Note that at the time of writing this document two useful fields (SA 92-248 and SA 98-1082) have not yet had new field centres and exposure times determined, but these OBs will be prepared as soon as possible. Their positions below are approximate, and the finder charts show the full EMMI field of view, which at  $9' \times 9'$  was considerably larger than the EFOSC2 FOV ( $4.1' \times 4.1'$ ).

Table 1: *Field centres for EFOSC2*

The accompanying finding charts have been taken directly with EFOSC2 – the bad columns of CCD#40 are visible, and it can be seen that the pointings have been chosen to keep stars away from them. The size of the field is  $4.1' \times 4.1'$ . North is at the top and East to the right, as indicated

by the arrow. Note that this is flipped horizontally compared with the view on sky, as this is the orientation of EFOSC2 images. These finder charts are also attached to the OBs and viewable from p2pp. The field centre, suggested exposure times and broad band photometry for each star appearing in the field, as listed by Landolt [1], are given in the table under each finding chart.

### 3 Definition of the OBs

The OBs were produced by finding the optimal pointing interactively, and choosing exposure times for each filter to avoid saturating the brightest stars in the best conditions (seeing FWHM=0.5") in 2x2 binning (the default mode). In poorer seeing the exposure times can be increased. The list of filters is:

- U#640, B#639, V#641, R#642, i#705

Exposures in filters not required on a particular night can be skipped by indicating it in the Broker of Observing Blocks (BOB), under the control of the instrument operator. This is usually more convenient than defining individual OBs for each filter.

### 4 Execution of the Calibrations

The calibration OBs for photometric standards are stored in `impex-stdcal-new/EFOSC2/PhotStds` on `wg5dhs` machine from where they can be imported into p2pp. They are also stored in an OT queue named `NTT_EFOSC2_CAL_PHOT_STD`.

The calibration OB is then fetched by BOB with all its contents, including the observation templates for filters that are not desired or even available in the setup. The selection of the individual templates to be executed (i.e., the filters which will be actually used in the observation) is done in BOB by the telescope operator, following the instructions of the astronomer. Alternatively, for a visitor run where only a subset of filters will be used, one can import the OBs into p2pp and delete the unnecessary columns in all the OBs before executing them. This has the advantage of reducing the overhead during the night as the telescope operator will simply run the whole OB.

### 5 Extended Standard Fields

Most of the Landolt fields are also included in the Stetson catalogue [3], which goes deeper and includes a number of the fainter stars in each of these fields. This catalogue is used by the automatic standard star measuring software installed on the NTT offline workstation `wg5off` (see below). There are therefore many Stetson stars within the fields defined by these OBs, however only the primary Landolt standards are marked in the finder charts. In addition to the equatorial standards we are also seeking to extend the list of OBs to the Southern Landolt standards (around -50 declination, including the popular T Phe field) [2], which are observable when the wind from the North limits the pointing of the NTT. These OBs will appear as they are ready in the calibration OB directory on `wg5dhs` and in the OT queues; this document will be updated to include them once a significant number of OBs are prepared.

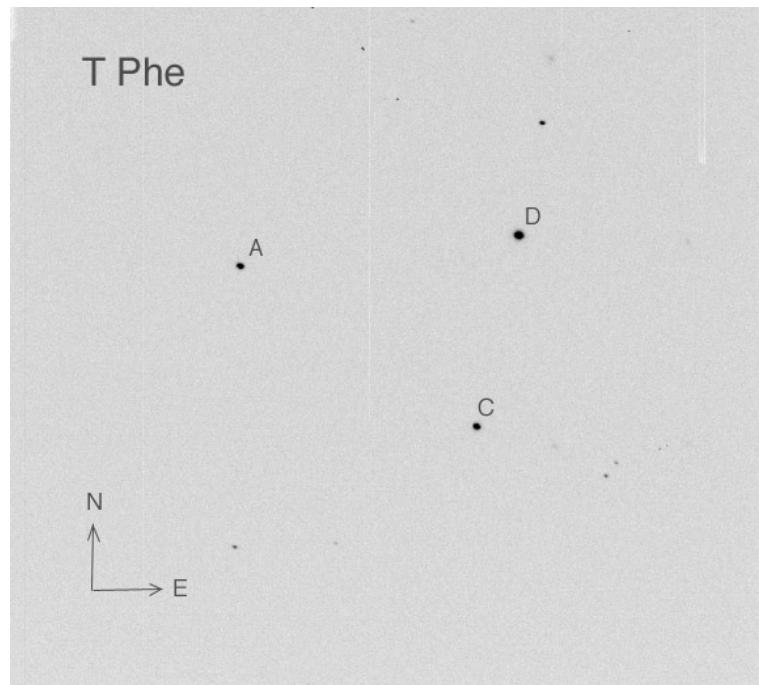

## 6 Automatic standard star photometry

Since EFSOC2 images now contain World Co-ordinate System (WCS) information, identifying standard stars within the field can be done directly by the RA and Dec position of each star. An automatic routine which identifies all Stetson and Landolt standard stars in each frame is available on the offline machine `wg5off`. This IRAF based routine identifies and measures the photometry for each star, and then solves for the zeropoint. It can run entirely without interaction to give an assessment of the photometric quality of the night (by comparison with known EFOSC2 zeropoints), or interactively to solve for zeropoints, extinctions and colour terms. Details are available on the webpage <http://www.eso.org/sci/facilities/lasilla/instruments/efosc/inst/zp>.
