Correlation Between Black Hole Mass and Bulge Mass

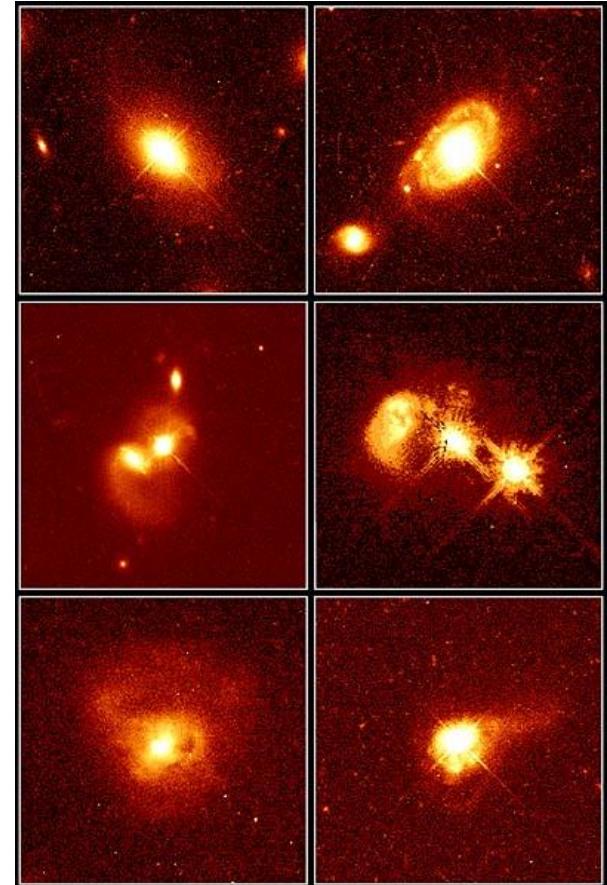

Galaxies, Black Holes, and Active Galactic Nuclei

- Black hole growth: accretion-- or AGN phase(s)
- How to activate (feed) a black hole?
- The usual suspect: major galaxy mergers
- AGN expected to live in mergers/spheroids
- Is this picture supported by observations?

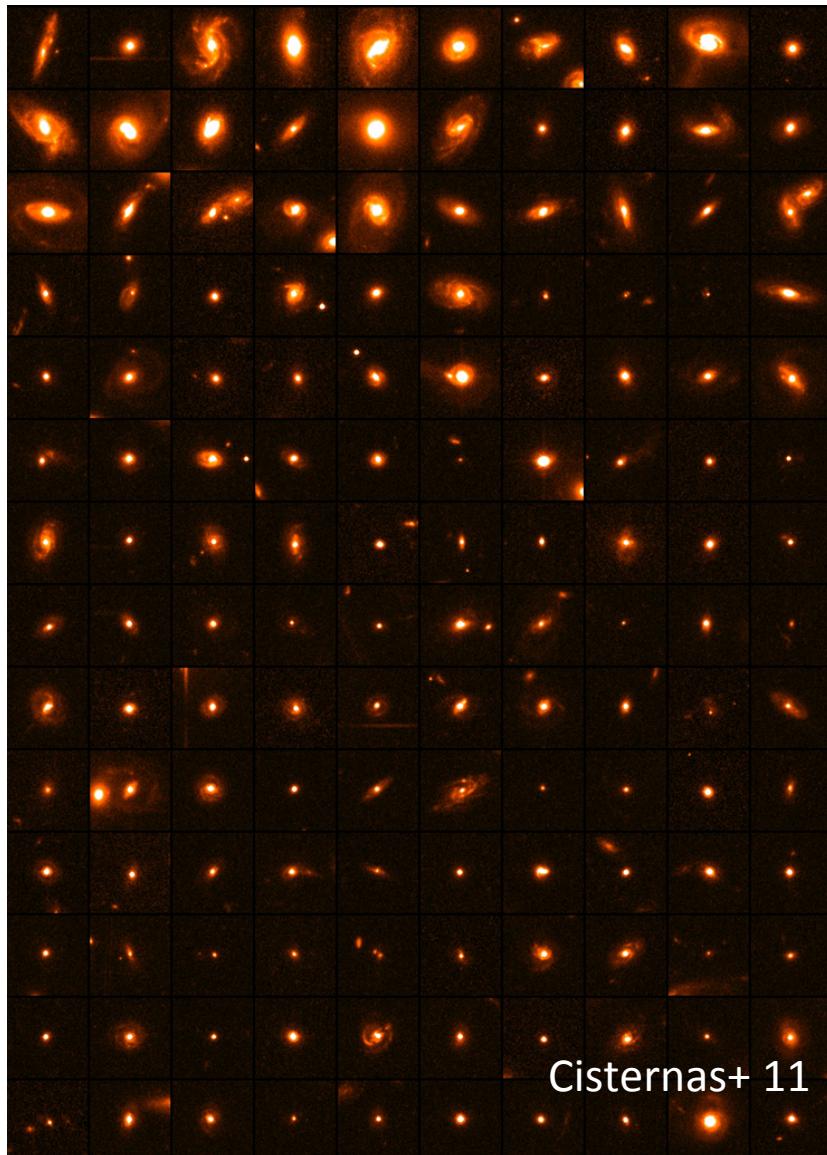

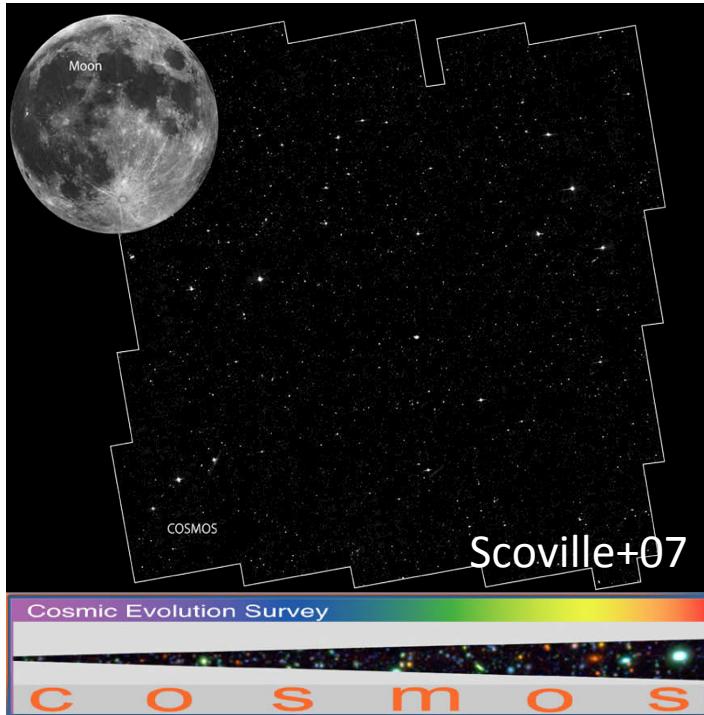

Di Matteo+ 05

Boyce+ 96; Bahcall+ 97

Recent Observational Results: COSMOS

- 2 deg²: Largest contiguous *HST* field
- Ancillary coverage from X-ray to radio
- *XMM-Newton*: large/clean AGN sample
- *HST/ACS*, F814W: optical morphologies out to z=1
- 140 X-ray selected AGN at $0.3 < z < 1.0$

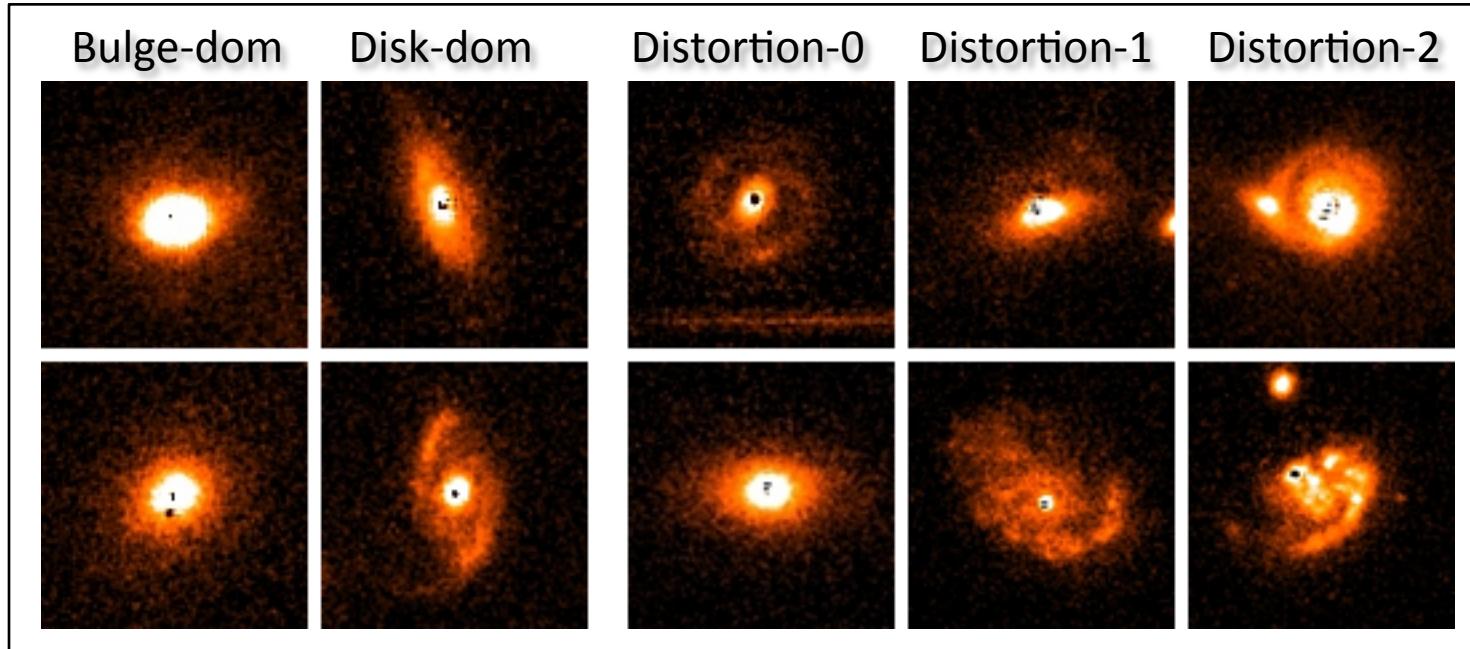

Cisternas+ 11

Recent Observational Results: COSMOS

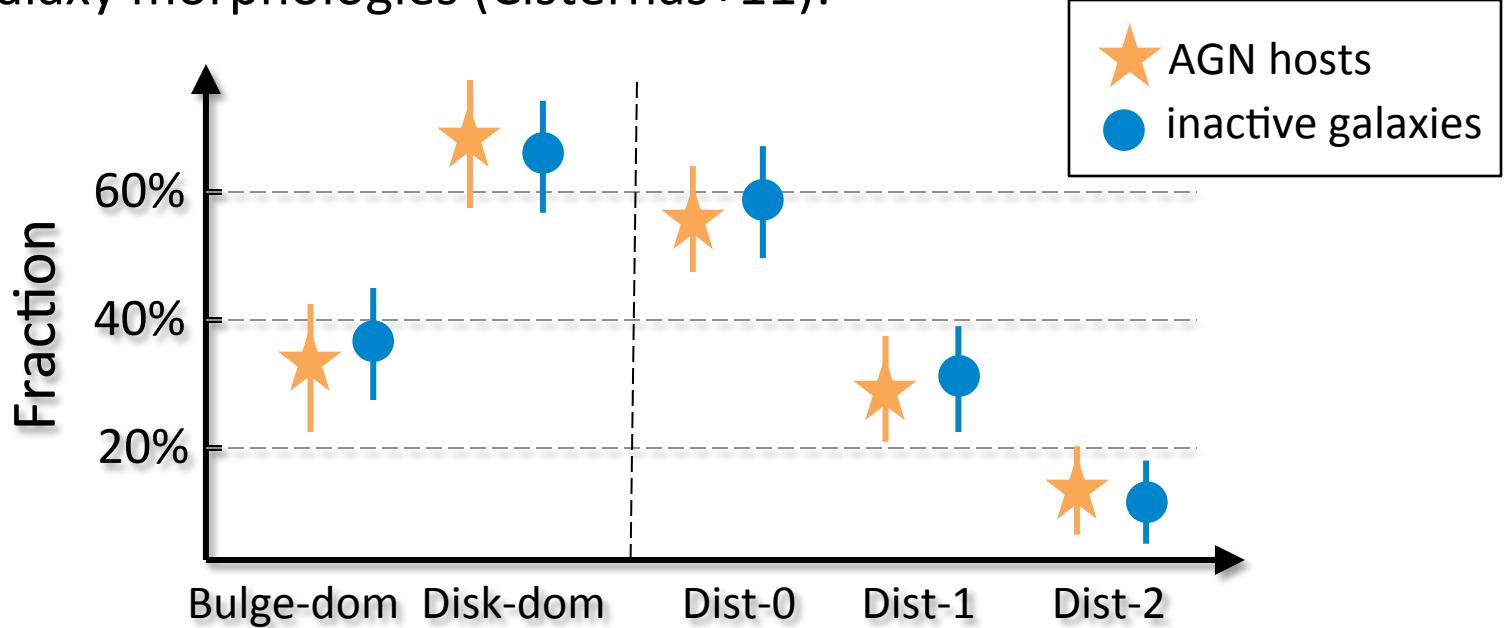

COSMOS AGN host galaxy morphologies (Cisternas+ 11)

- Visually classified according to:
 - Hubble type: Bulge- or disk-dominated
 - Distortion level: smooth, mildly distorted, or wrecked
- Direct comparison to matched inactive galaxies

Recent Observational Results: COSMOS

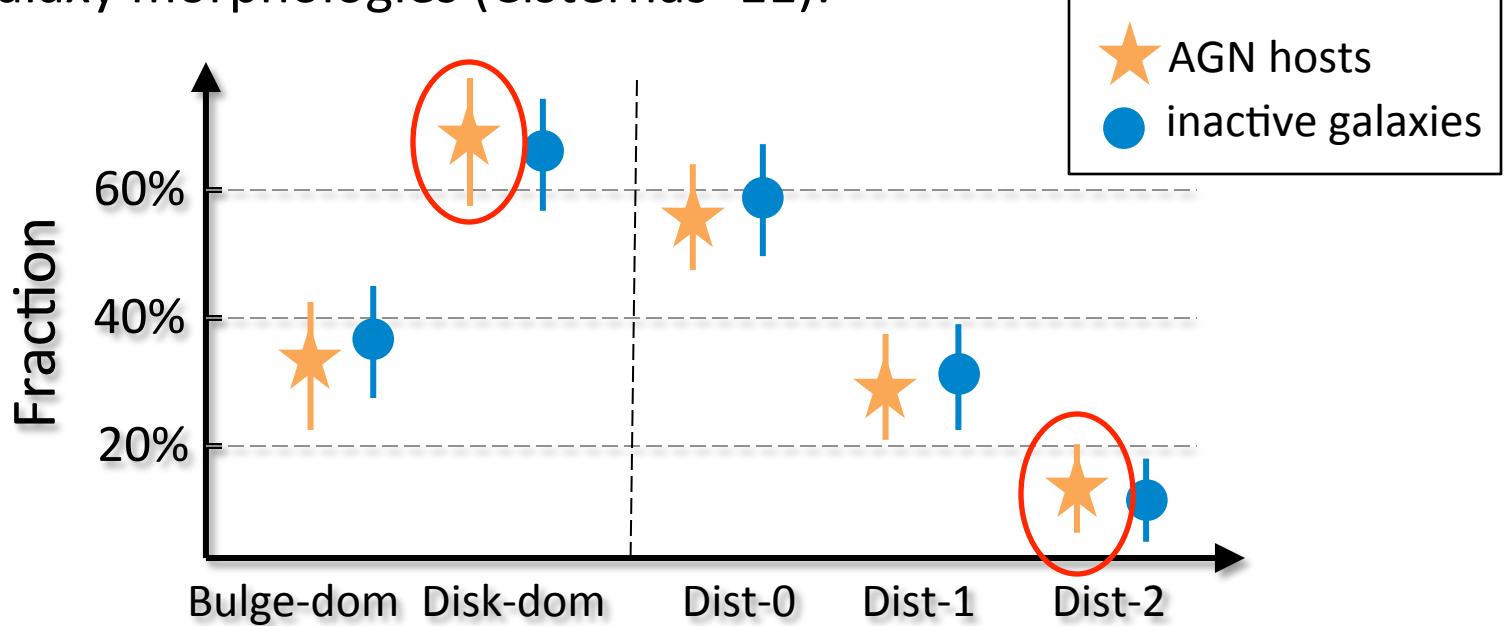

AGN host galaxy morphologies (Cisternas+11):

1. Only a minority (~15%) of AGN found in merging systems...
2. ... consistent with the merger rate of “normal” galaxies
3. Most AGN (65%) reside in disk-dominated galaxies

Recent Observational Results: COSMOS

AGN host galaxy morphologies (Cisternas+11):

1. Only a minority (~15%) of AGN found in merging systems...
2. ... consistent with the merger rate of “normal” galaxies
3. Most AGN (65%) reside in disk-dominated galaxies

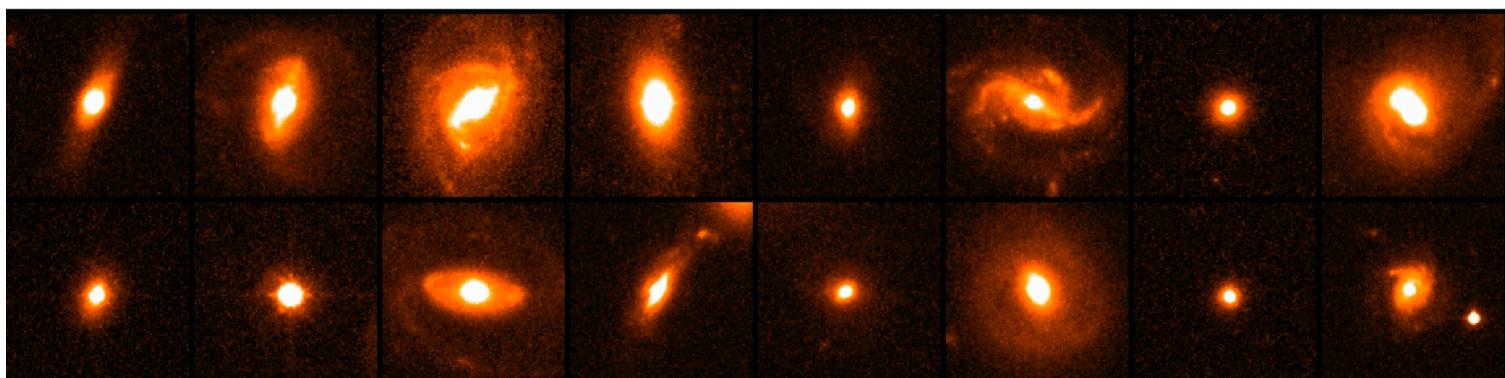

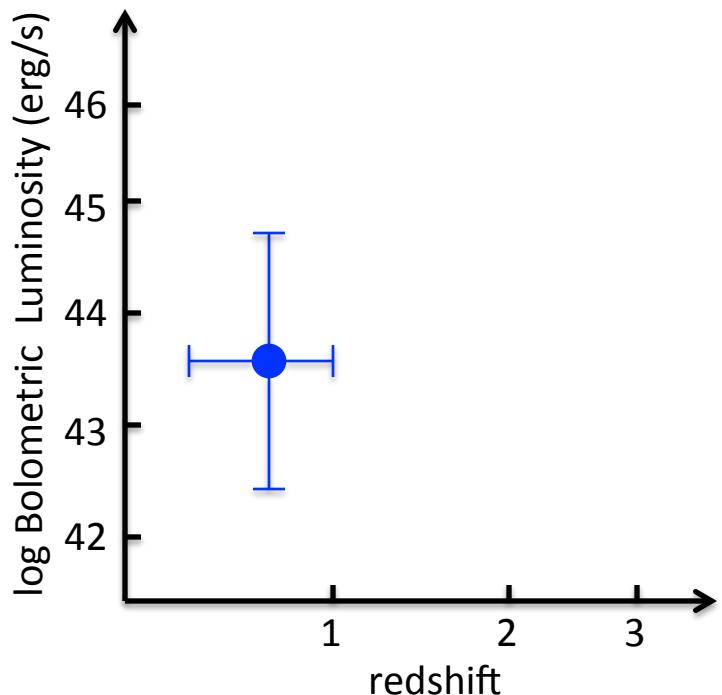

Recent Observational Results: COSMOS

AGN host galaxy morphologies:
mostly disk and undisturbed

Surprising?

Parameter space:

- relatively "local"
- at $z < 1$, universe is rather secular
- much more action at $z \sim 2$

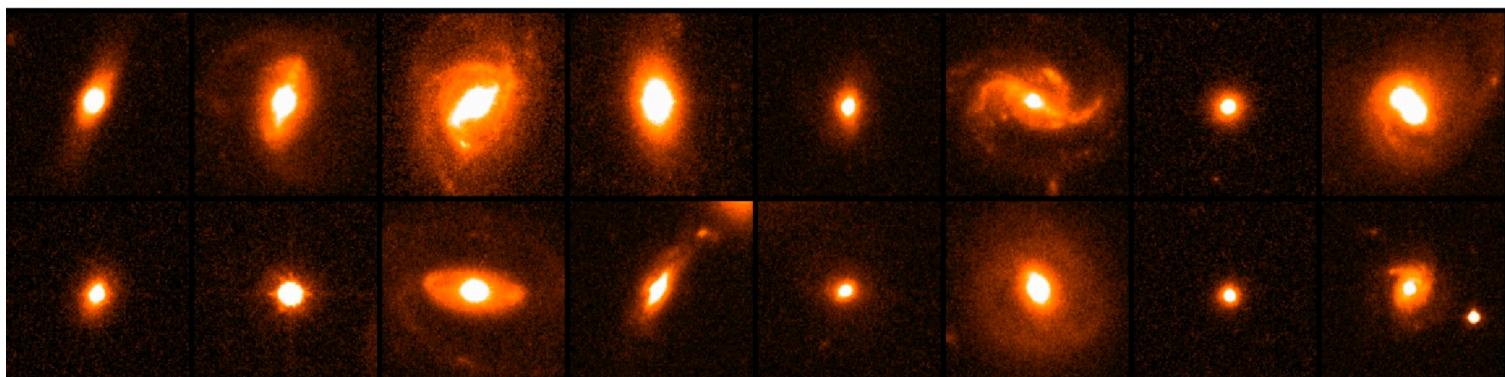

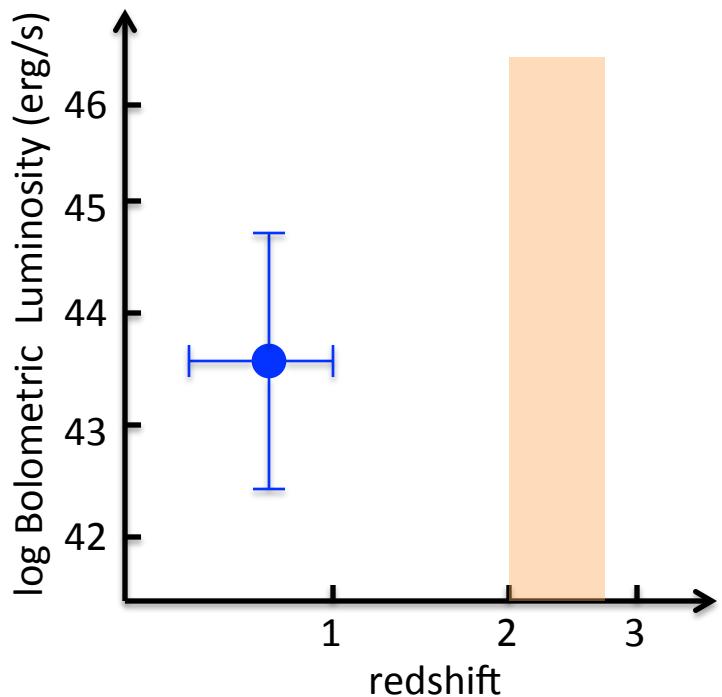

Recent Observational Results: COSMOS

AGN host galaxy morphologies:
mostly disk and undisturbed

Surprising?

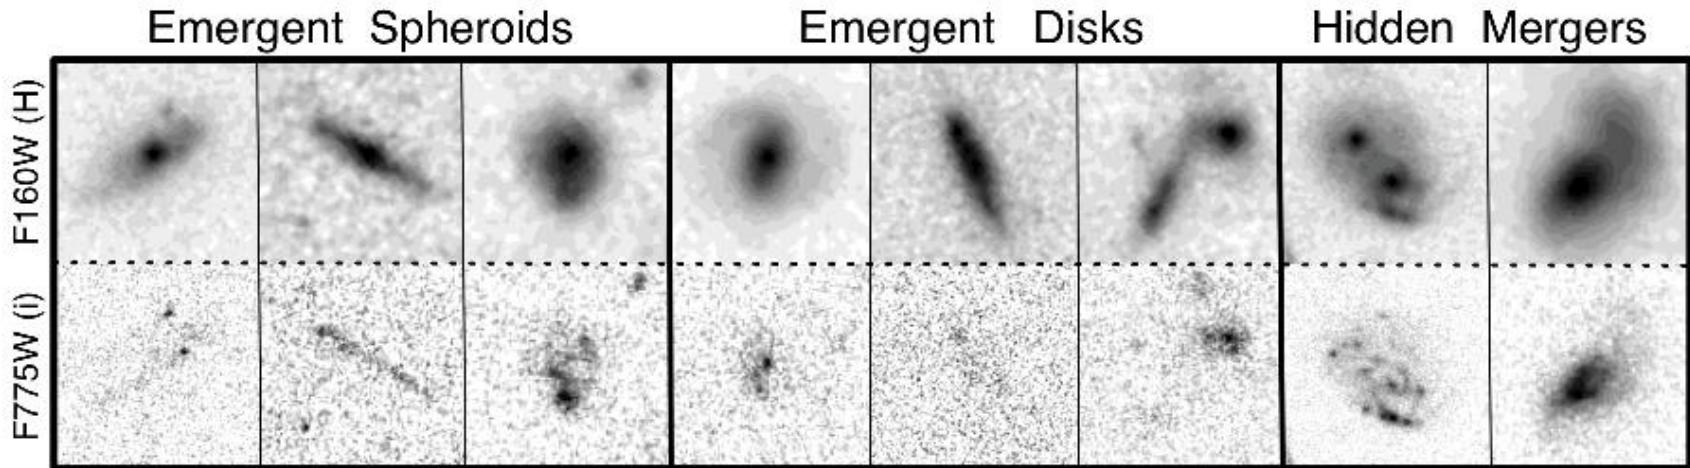

Parameter space:

- relatively "local"
- at $z < 1$, universe is rather secular
- much more action at $z \sim 2$

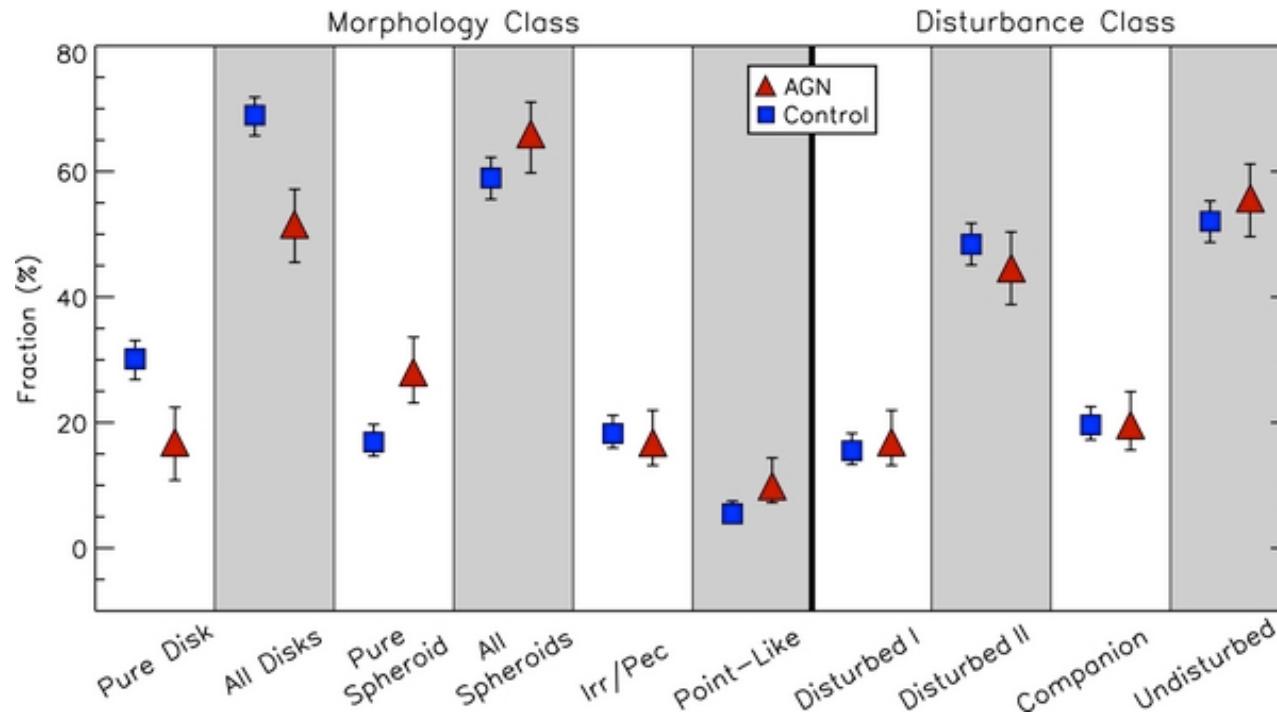

Recent Observational Results: CANDELS

- Largest HST program (PIs: Faber, Ferguson)
- Deep (GOODS) and wide (COSMOS, UDS, EGS) surveys
- WFC3 (J and H): optical morphologies at $z \sim 2$
- 72 AGN in the CDF-S at $1.5 < z < 2.5$

Recent Observational Results: CANDELS

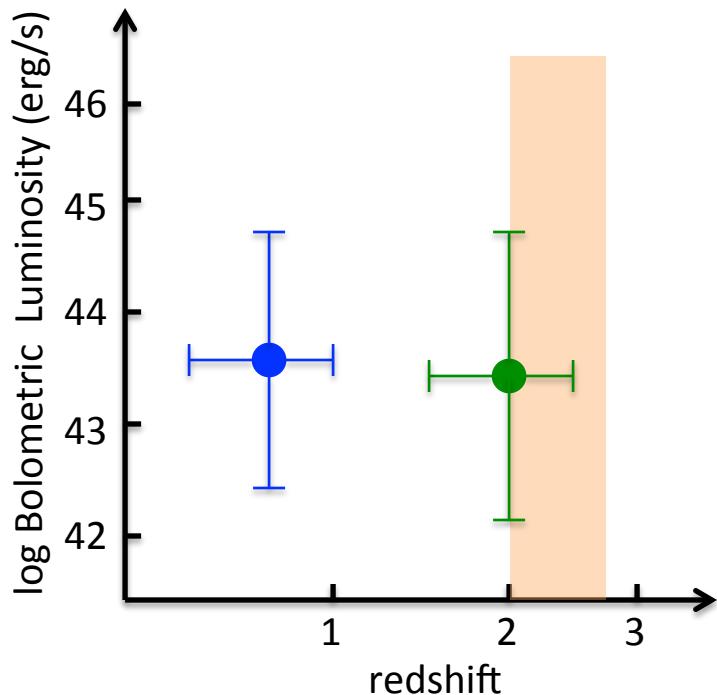

AGN host galaxy morphologies, now at $z \sim 2$ (Kocevski+12)

1. Only a minority ($\sim 17\%$) of AGN found in merging systems...
2. ... consistent with the merger rate of “normal” galaxies
3. Significant fraction of AGN hosted by disks

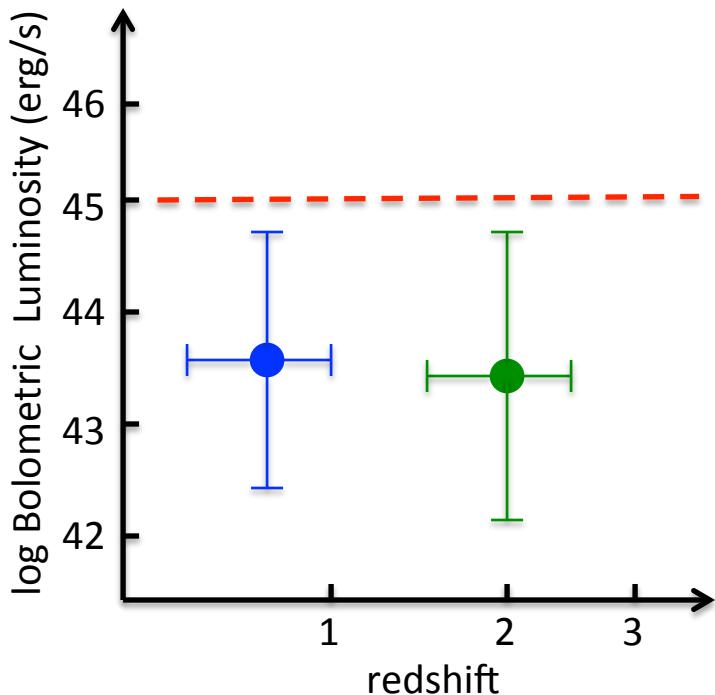

Where to find enough quasars?

- Equivalent results from both COSMOS and CANDELS
- Luminosities probed: just below quasar cutoff
- Small area surveys: very few quasars
- SDSS: tens of thousands of QSOs...
... but: shallow, arcsec resolution
- Bright quasar dominates the overall light distribution

Where to find enough quasars?

- Equivalent results from both COSMOS and CANDELS
- Luminosities probed: just below quasar cutoff
- Small area surveys: very few quasars
- SDSS: tens of thousands of QSOs...
... but: shallow, arcsec resolution
- Bright quasar dominates the overall light distribution

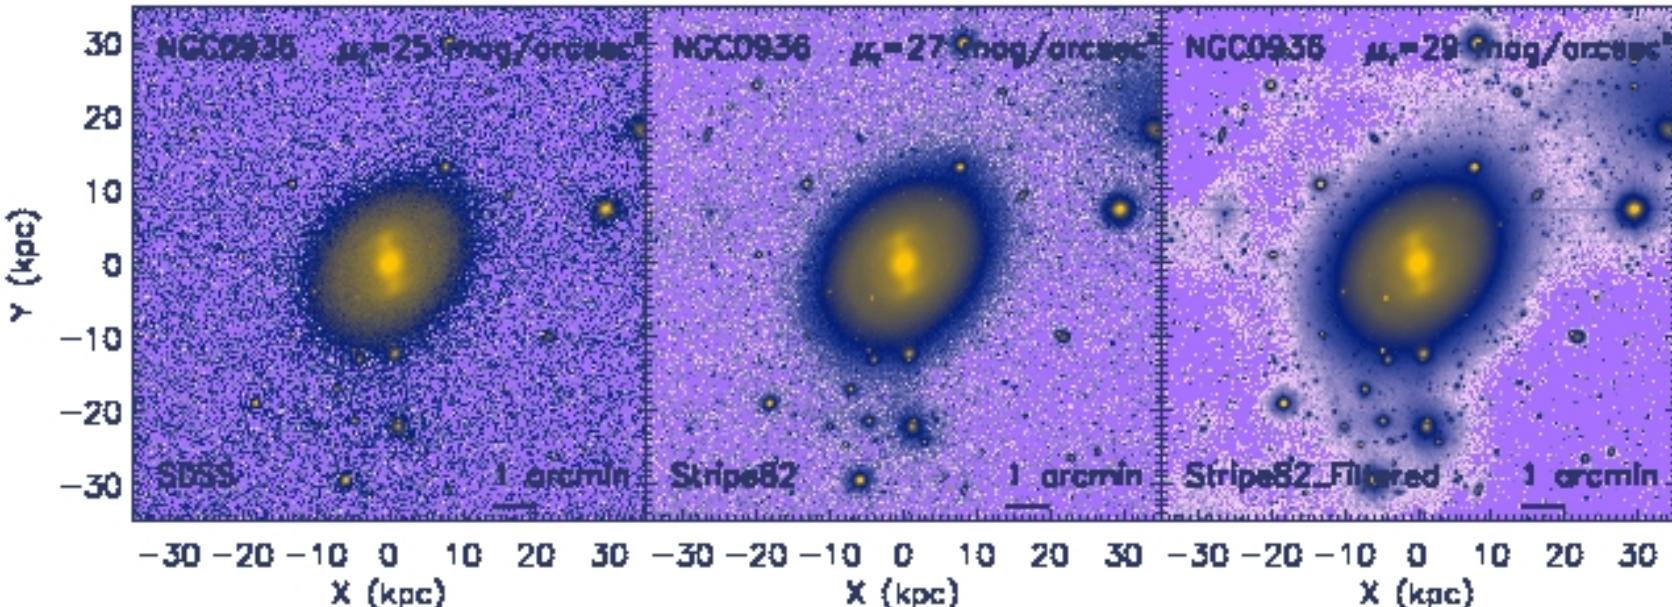

IAC Legacy Stripe82 co-add (Fliri & Trujillo '14)

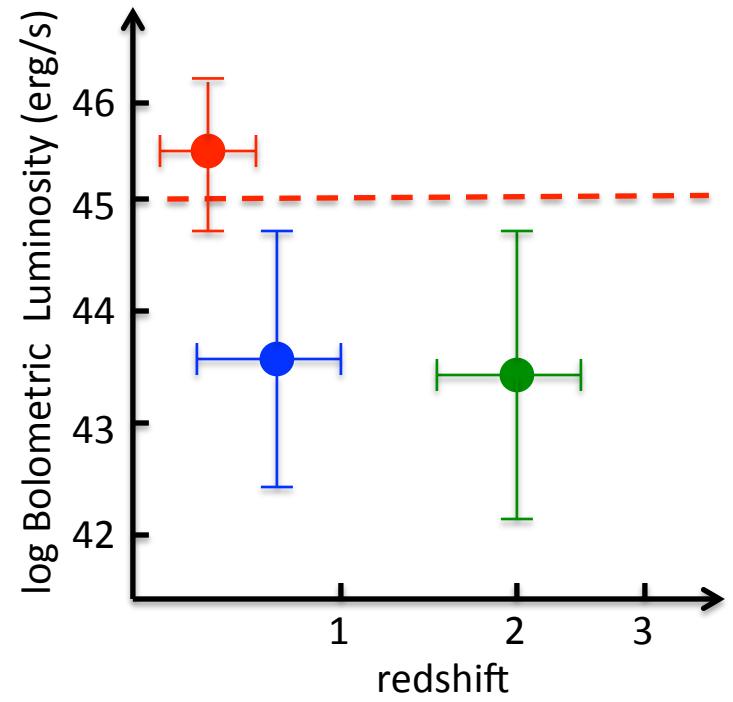

www.iac.es/proyecto/stripe82

- SDSS Stripe 82: 275 deg² equatorial stripe observed ~80 times
- IAC S82 project: produce a co-add of only the *best* images
- 50% of images thrown away due to: bright sky, major sky gradients, poor seeing, clouds
- Result: extremely flat sky; 2 mag deeper than standard SDSS

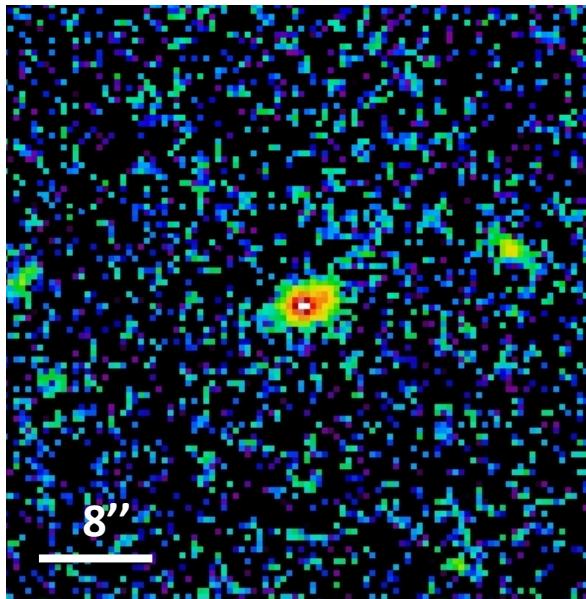

QSOs in Stripe 82

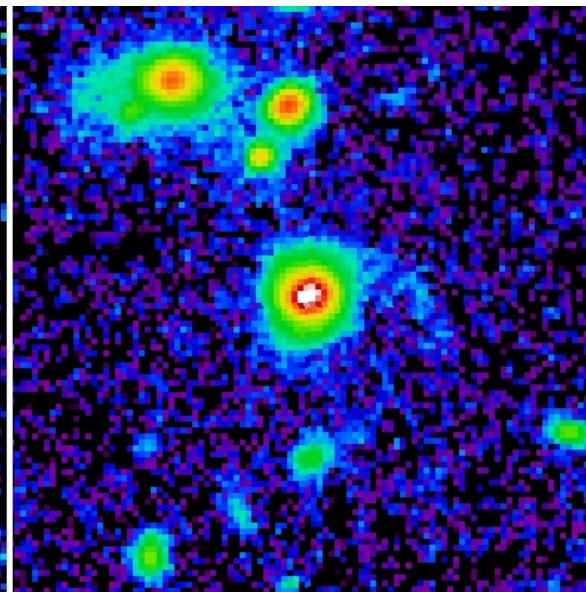

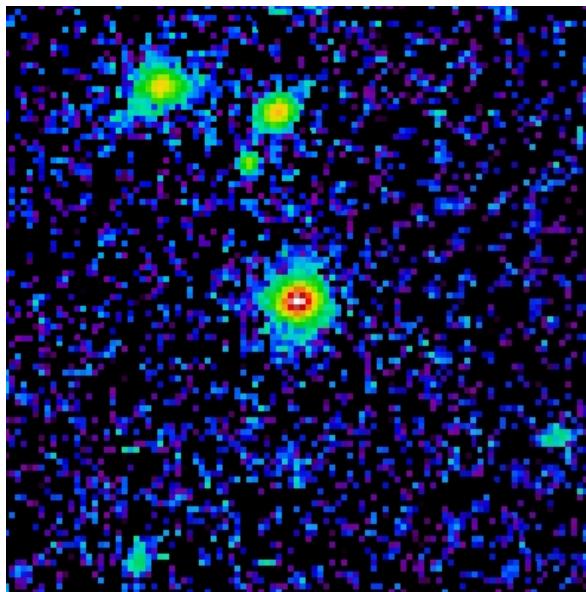

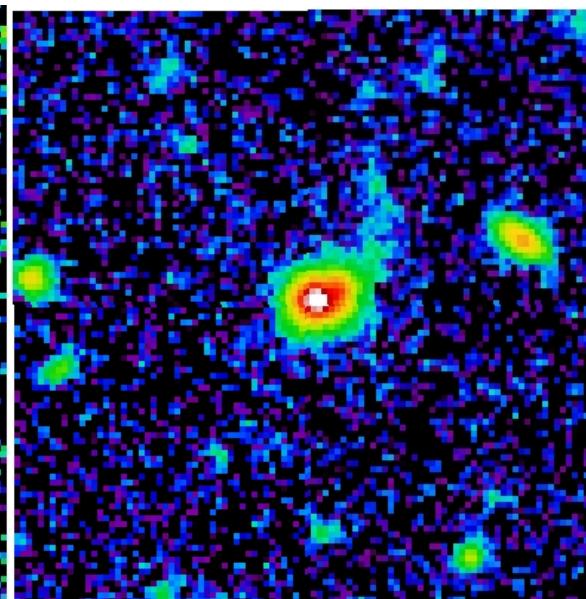

- DR7 quasar catalog (Schneider+10)
- 352 quasars in S82

SDSS single epoch

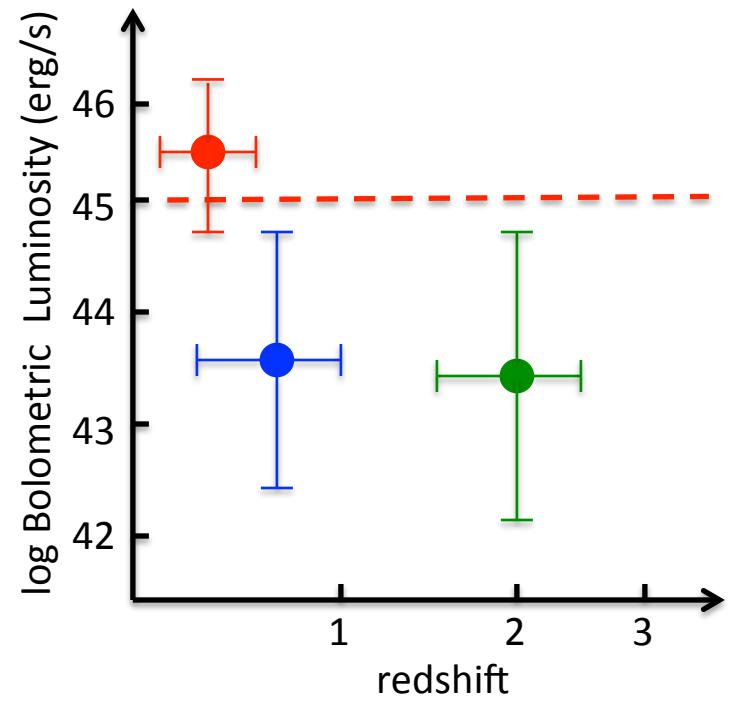

Stripe 82 co-add

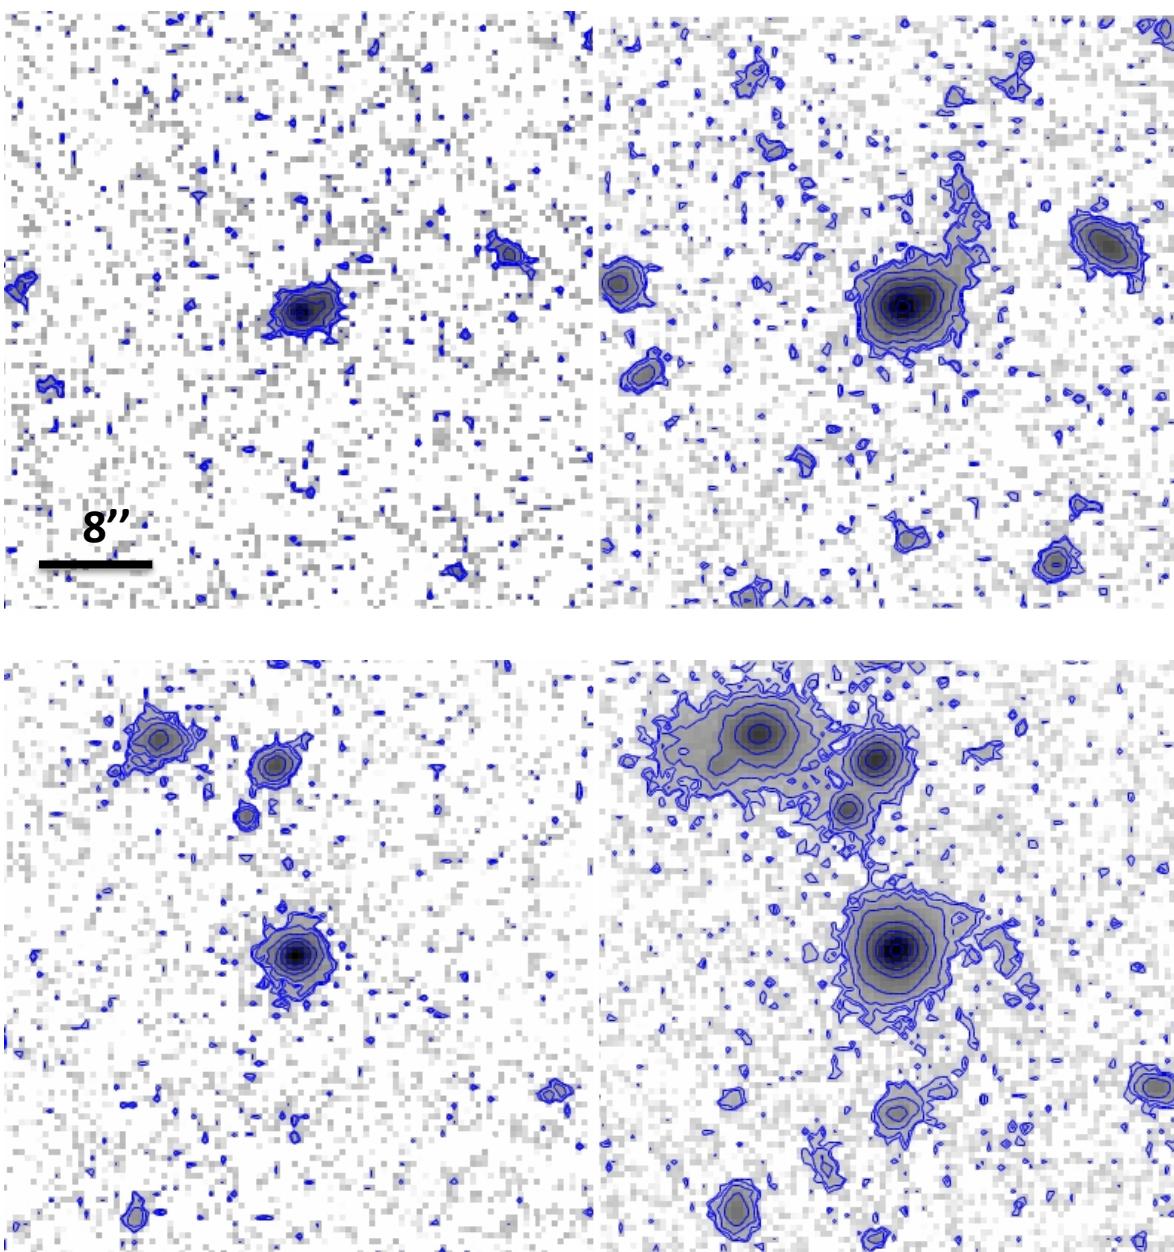

QSOs in Stripe 82

- DR7 quasar catalog (Schneider+10)
- 352 quasars in S82

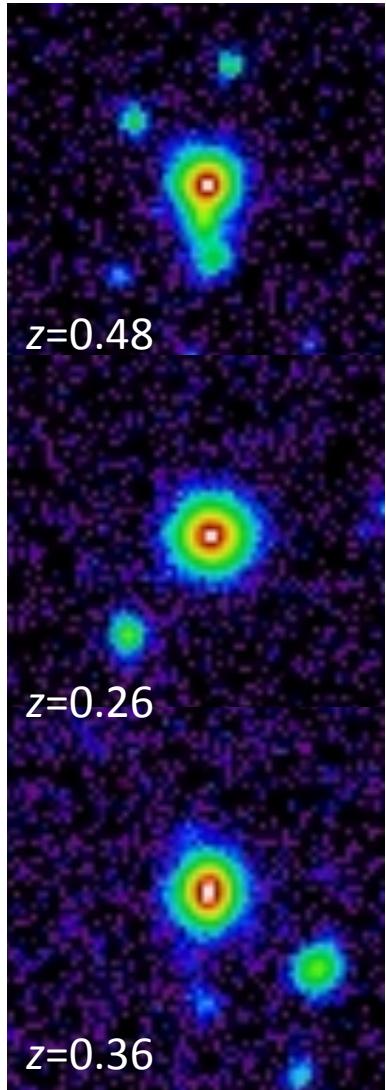

SDSS single epoch

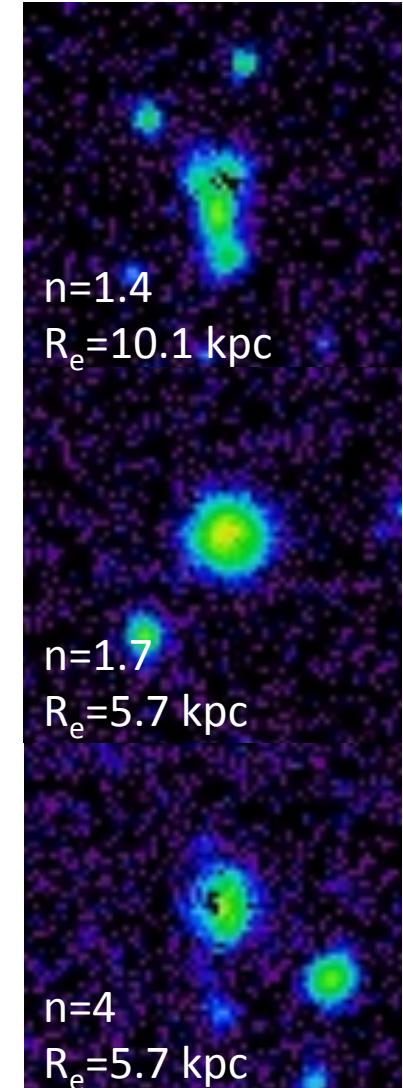

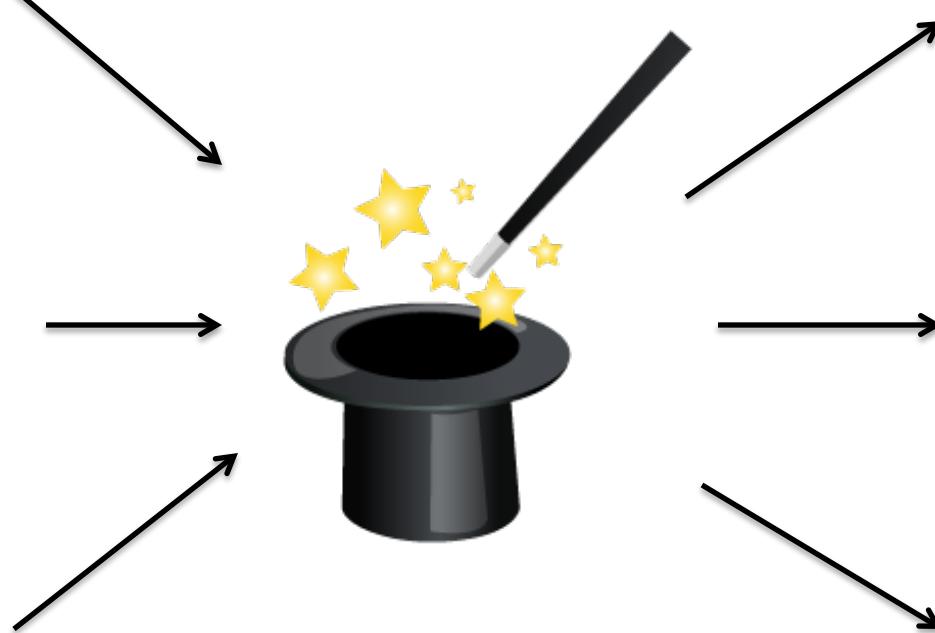

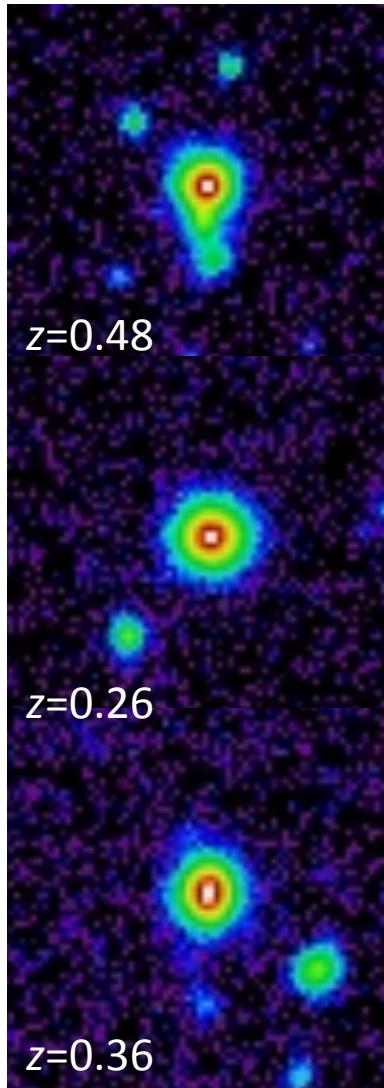

Stripe 82 co-add

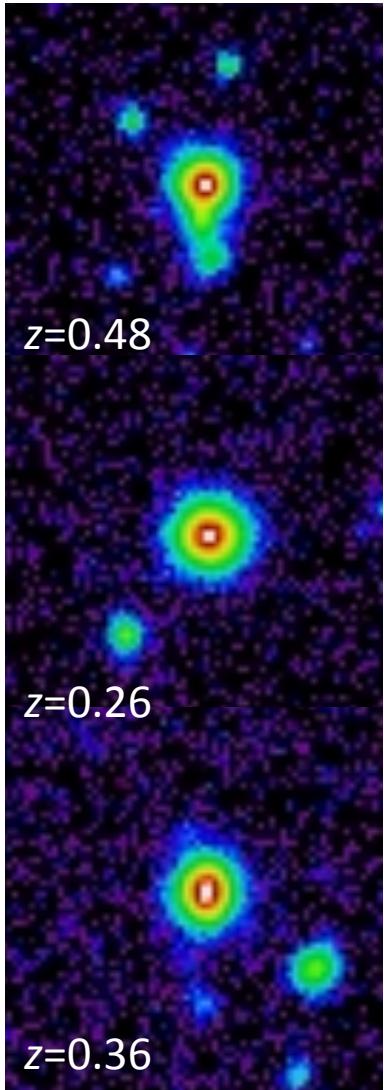

Revealing the hidden quasar host galaxies

Revealing the hidden quasar host galaxies

Revealing the hidden quasar host galaxies

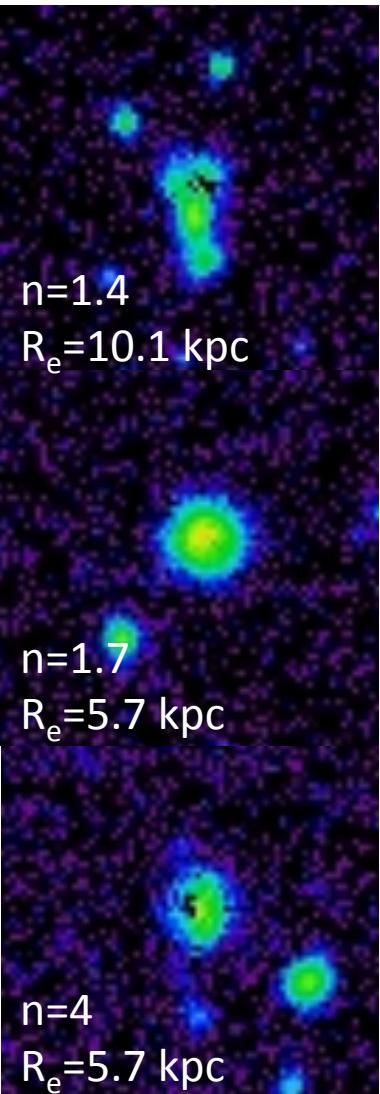

Represent QSO as PSF+Sersic profile

Custom-made PSFs from 100+ stars

2D fitting with GALFIT

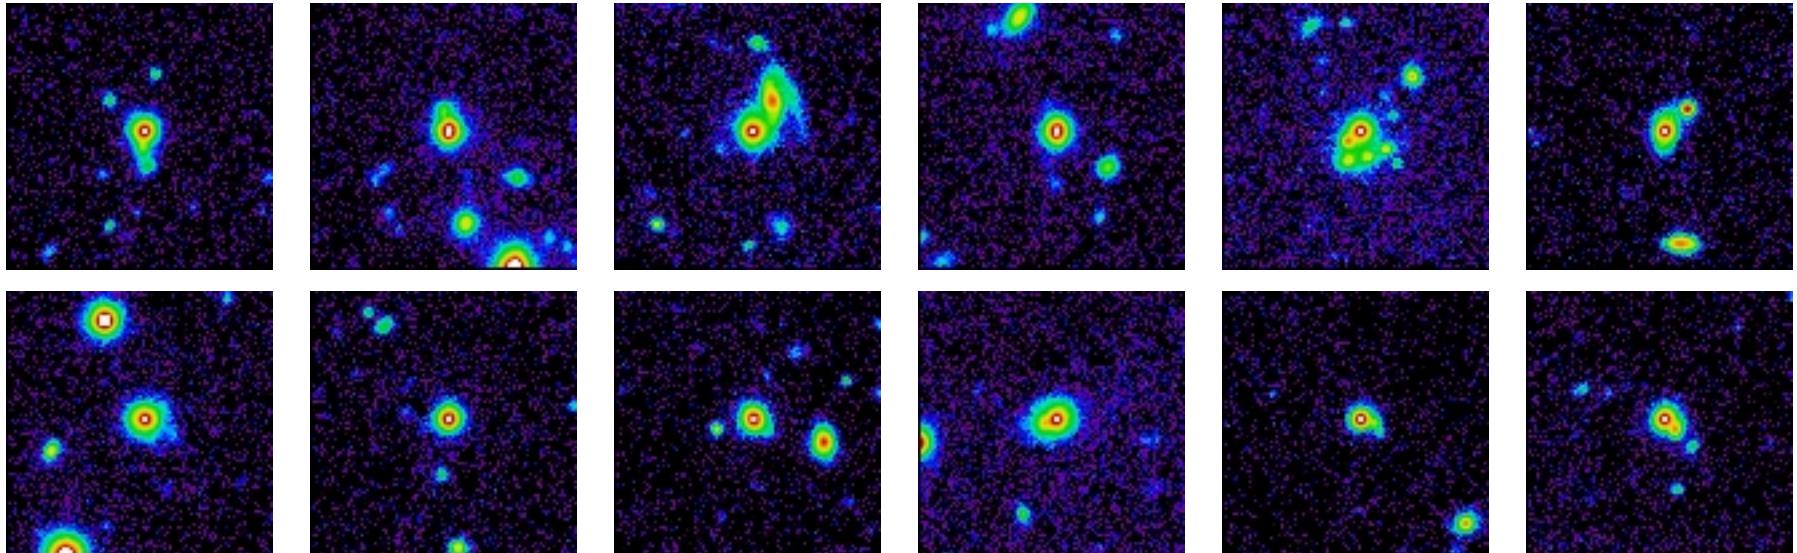

Careful assessment of resulting parameters
(e.g., Sersic $n=20$, $R_e=0.001''$, etc)

...

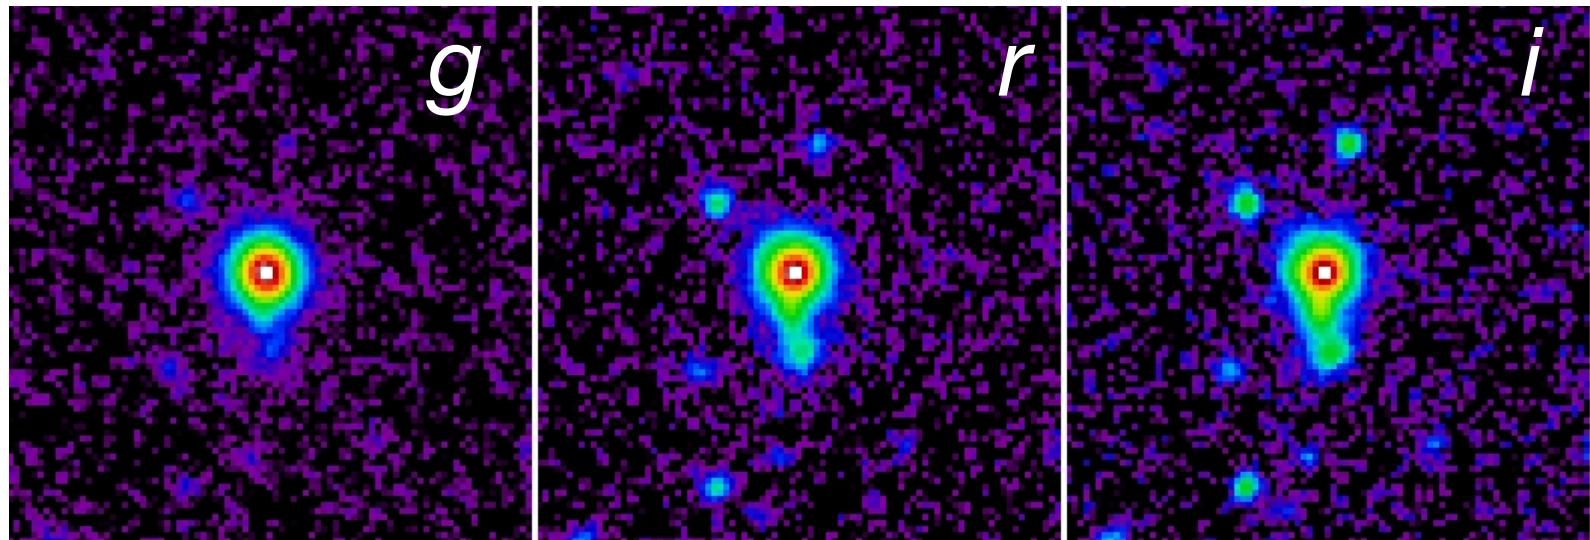

(Preliminary) Results: quasar host galaxies

- 3% not suitable to fit, 15% unresolved
- 50% disks, 36% spheroids, remaining intermediate morphologies
- At least 35% unambiguously interacting/merging

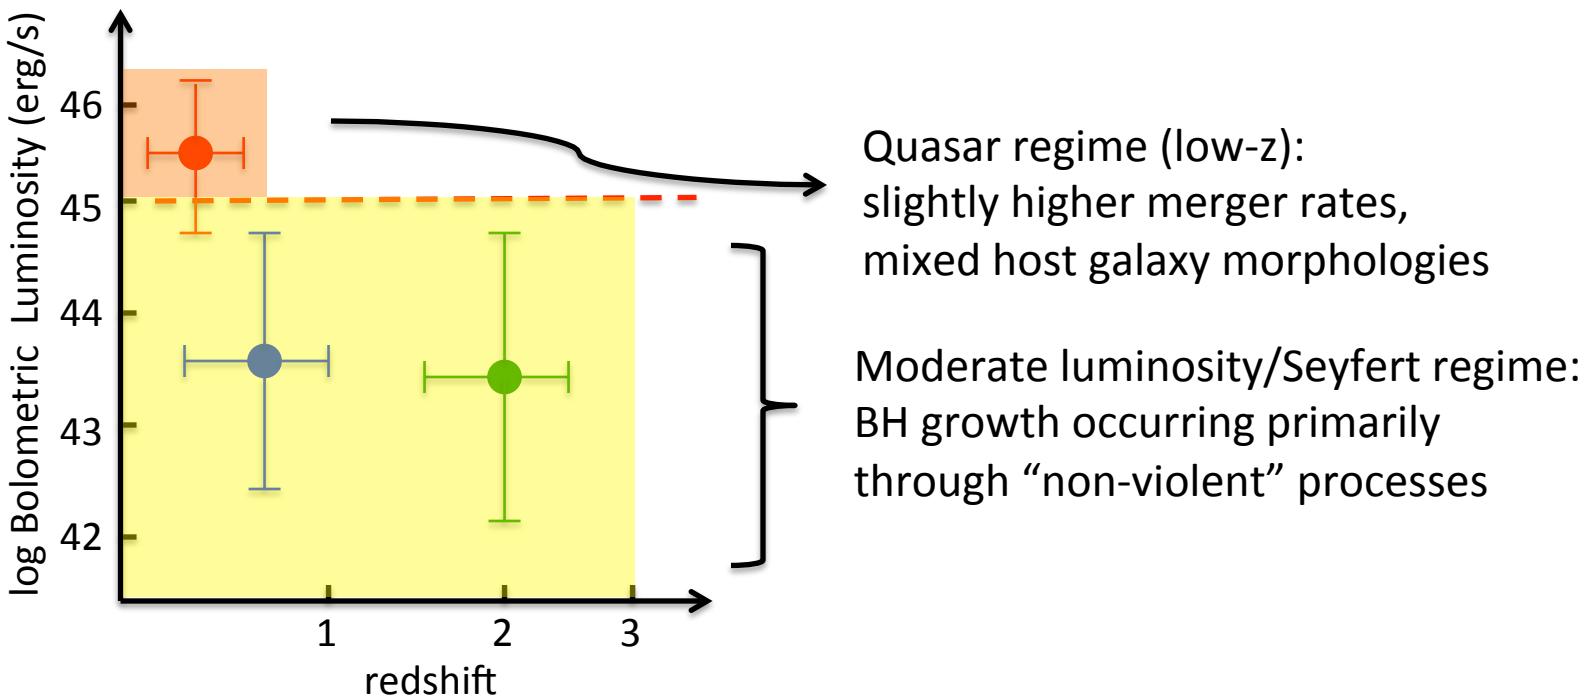

Future work with Stripe82

- Multiband decompositions to investigate, e.g.,:
 - SF properties of host galaxies
 - Gas-richness of merger features

- Compare QSO host galaxies to similar inactive galaxies

Summary: oversimplified picture

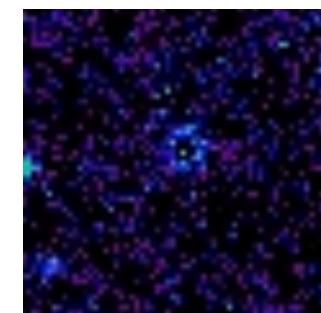

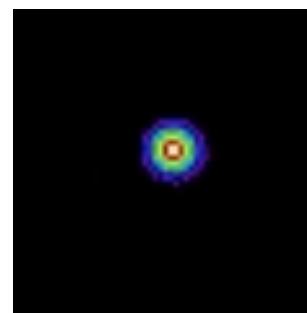

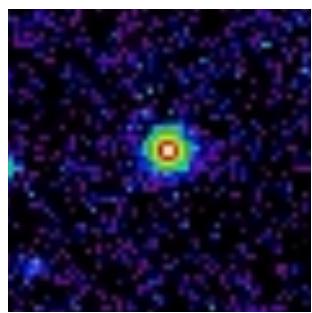

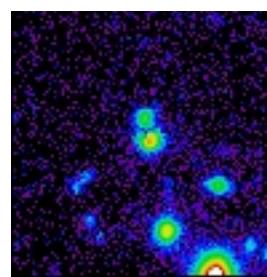

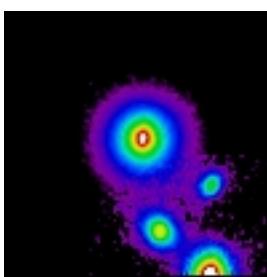

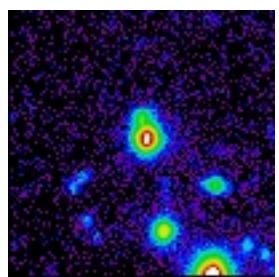

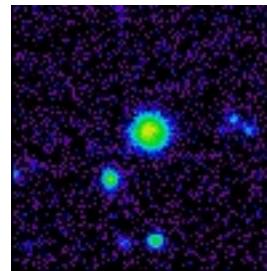

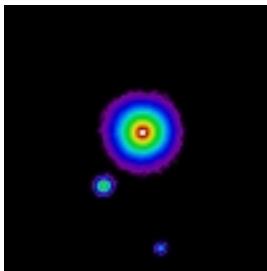

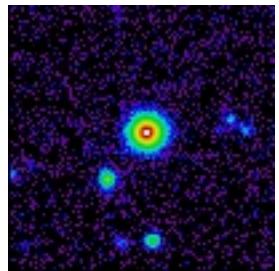

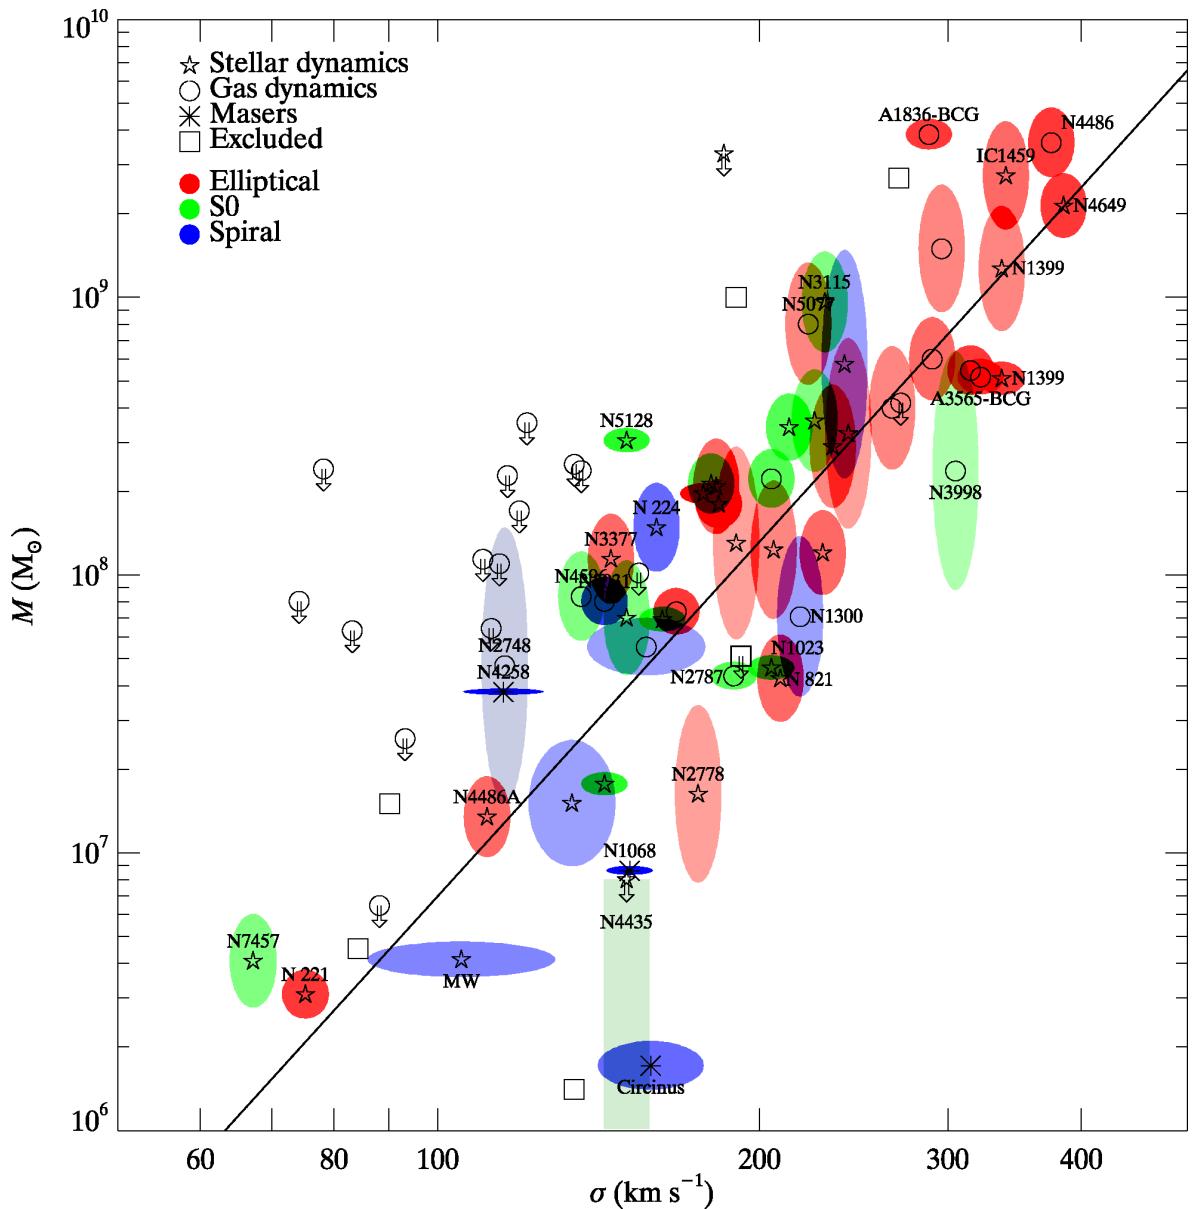

Quasar regime (low-z):
slightly higher merger rates,
mixed host galaxy morphologies

Moderate luminosity/Seyfert regime:
BH growth occurring primarily
through “non-violent” processes

Open question: what parameters reflect the origin of the AGN activity?

(redshift, luminosity, BH accretion rate, stellar mass, gas fractions, ...)
